Nutrition Economics – An Introduction

Karen Freijer, BHS*, Nutritionist and PhD candidate, School for Public Health and Primary Care (CAPHRI), Maastricht University, Maastricht, The Netherlands; Irene Lenoir-Wijnkoop, MS*, Associate Professor Public Health Nutrition, Department of Pharmaceutical Sciences, Utrecht University, Utrecht, The Netherlands; Mark JC Nuijten, MD, PhD, Health Economist Consultant, Ars Accessus Medica, Jisp, The Netherlands; Silvia MAA Evers, PhD, Professor of Public Health Technology Assessment, School for Public Health and Primary Care (CAPHRI) of the Faculty of Health, Medicine and Life Sciences, Department of Health Services Research, Maastricht University, Maastricht, The Netherlands; Trimbos Institute, Netherlands Institute of Mental Health and Addiction, Utrecht, The Netherlands; Elizabeth L. Molsen, RN, Director, Scientific & Health Policy Initiatives International Society for Pharmacoeconomics & Outcomes Research (ISPOR), Lawrenceville, NJ, USA

Key Points

- Nutrition Economics focuses on the interdependency between nutritional habits, health, and public expenses.
- There is no systematic approach or specific methodology to assess the impact of nutrition on health and health-related quality of life despite a clear need from policy makers.
- The establishment of an ISPOR Nutrition Economics Special Interest Group is underway to develop recommendations on economic evaluations to describe and quantify the costs (both the immediate costs of the intervention and downstream consequences) and effectiveness of nutrition interventions, as well as to assess the impact for individuals, the health care system, and society as a whole regarding disease-related malnutrition (DRM) as the initial focus.

Nutrition economics, as the name implies, is the merging of the nutrition and health economics disciplines to assess the impact of nutrition on health and disease and to illustrate the health and economic aspects of specific changes in the daily nutrition and nutrition recommendations through the lens of cost effectiveness. Nutrition economics is defined as “a discipline dedicated to researching and characterizing health and economic outcomes in nutrition for the benefit of society” [1]. This rising research field focuses on the interdependency between nutritional habits, health, and public expenses. It supports nutrition, health economics, and health policy development in an evidence- and health-benefit-based manner [1]. It will increase the understanding of nutrition’s impact on health outcomes and of its absolute and relative monetary effect.

The nutrition field is extremely broad, with interventions from individual treatments to broad public health measures. Answers are needed to questions such as: How should the cost and effectiveness of nutrition interventions be quantified? How would one assess their impact on the individual, the health care system, and society as a whole?

Until now, no systematic approach or specific methodology has been developed to assess the impact of nutrition on health and health-related quality of life despite a clear need from policy makers. There are many challenges in nutrition assessment, from the difficulty in establishing a correlation between a product’s consumption and future health status, to confounding factors and special methodological considerations, such as those encountered when assessing medical devices for reimbursement [2-4]. Economic evaluation will require a range of different approaches that compare nutrition-related costs to health outcomes, in order to sustain value-based decisions within systems providing health care.

With the increasing number of nutrition-related interventions and the consequent number of (economic) evaluations, the time has come to establish a group to develop preliminary scientific guidelines for nutrition economic assessments and outcomes research. To this end, ISPOR is initiating a Nutrition Economics Special Interest Group (SIG). This initiative is already supported by a group of leading experts in the fields of nutrition, medicine, pharmacology, epidemiology, and health economics. The SIG’s initial focus will be on recommendations for the economic evaluation of disease-related malnutrition (DRM), meaning under-nutrition in health care [5-7].

The causes of DRM are multi-factorial. The metabolic stress on the body due to an acute or chronic disease resulting in catabolism is one of the most important and prevalent [8]. The effects of DRM can complicate the disease process by: weakness/fatigue, impaired functioning of organs, such as the heart, lungs, and GI system, and slower wound healing. Any of these effects results in a greater chance for clinical complications [7,8].

DRM thus leads to the increased likelihood of patient complications, as potential (re-) admission(s), and length(s) of hospital stay(s). Any of these results is associated with higher health care costs [8-9]. It has been calculated that approximately 33 million patients in Europe are suffering from DRM, at an estimated cost of €170 billion [11,12]. This is more than double the amount of money spent on obesity, based on figures from the UK [13].

Improvement in the quality or quantity of food supplied can ameliorate this type of under-nutrition. Unfortunately, in many cases, the patient cannot or will not consume a sufficient amount of nutrients needed to meet their increased nutritional requirements.

In the case of a disease treatment, it is important to consider additions to their daily nutrition or alternatives to improve nutritional intake, such as medical nutrition. Medical nutrition comprises parenteral nutrition (regulated in pharmaceutical legislation), as well as all forms of enteral nutritional support that are regulated as “foods for special medical purposes” (FSMP), as defined by the European Commission Directive 1999/21/EC, independent of the route of application [14].

FSMP is a special category for food that is intended for the dietary management of patients. This food is specially processed or formulated and used under medical supervision. FSMP products include oral nutritional supplements (ONS), as well as enteral tube feeding (ETF) via nasogastric, naso-enteral, or percutaneous tubes. These products contain regulated minimum and maximum levels of macro (carbohydrates, protein, fat) and micro (vitamins, minerals, trace-
Nutrition economics, as the name implies, is the merging of the nutrition and health economics disciplines to assess the impact of nutrition on health and disease and to illustrate the health and economic aspects of specific changes in the daily nutrition and nutrition recommendations through the lens of cost-effectiveness.

In conclusion, improving health care through better (medical) nutrition may contribute to the cost-effectiveness and sustainability of health care systems. Therefore, it is essential to describe and quantify the costs (both the immediate costs of the intervention and downstream consequences) and effectiveness of nutrition interventions, as well as to assess the impact for individuals, the health care system, and society as a whole. The establishment of an ISPOR Nutrition Economics Special Interest Group is underway to develop recommendations on economic evaluations in this emerging scientific field.

More information on this initiative will become available in future ISPOR publications and communications.

WEB CONNECTIONS
Researching world health expenditures? Want to know what countries are spending on the health care of their populations? The WHO’s Global Health Observatory (GHO) has exactly what you need: http://www.who.int/gho/health_financing/en/. One can quickly find country specific data regarding health care funding such as per capita expenditure and out of pocket expenditure. For some countries, data availability dates back to 1995 and through 2012. Dig through the data: you will be amazed at how much exists and the flexibility to find exactly what you need.
